Efficient Algorithms

Theories

- If we can find a fast low-rank factorization

$$\underbrace{\mathbf{K}}_{n \times n} \approx \underbrace{\mathbf{D}}_{n \times d} \underbrace{\mathbf{D}^T}_{d \times n},$$

then $(\mathbf{K} + \alpha \mathbf{I}_n)^{-1}$ and the partial eigenvalue decomposition of \mathbf{K} can be approximated solved highly efficiently.

How to Speedup: Example 1

Efficient Algorithms
Theories

- Suppose we have a low-rank factorization

$$\underbrace{\mathbf{K}}_{n \times n} \approx \underbrace{\mathbf{D}}_{n \times d} \underbrace{\mathbf{D}^T}_{d \times n}.$$

- Approximately compute the matrix inverse $(\mathbf{K} + \alpha \mathbf{I}_n)^{-1}$ as follows.
- Expand $(\mathbf{D}\mathbf{D}^T + \alpha \mathbf{I}_n)^{-1}$ using the Sherman-Morrison-Woodbury formula and obtain

$$(\mathbf{D}\mathbf{D}^T + \alpha \mathbf{I}_n)^{-1} = \alpha^{-1} \mathbf{I}_n - \alpha^{-1} \underbrace{\mathbf{D}}_{n \times d} \underbrace{(\alpha \mathbf{I}_d + \mathbf{D}^T \mathbf{D})^{-1}}_{d \times d} \underbrace{\mathbf{D}^T}_{d \times n}.$$

It costs only $\mathcal{O}(nd^2)$ time and $\mathcal{O}(nd)$ space to compute

$$\mathbf{b} = (\mathbf{D}\mathbf{D}^T + \alpha \mathbf{I}_n)^{-1} \mathbf{y}.$$

Efficient Algorithms
Theories

- Suppose we have a low-rank factorization

$$\underbrace{\mathbf{K}}_{n \times n} \approx \underbrace{\mathbf{D}}_{n \times d} \underbrace{\mathbf{D}^T}_{d \times n},$$

- Compute the eigenvalue decomposition of \mathbf{K} as follows.
- Compute the eigenvalue decomposition of the $d \times d$ small matrix $\mathbf{S} = \mathbf{D}^T \mathbf{D} \in \mathbb{R}^{d \times d}$:

$$\mathbf{S} = \mathbf{U}_S \mathbf{\Lambda}_S \mathbf{U}_S^T.$$

The partial eigenvalue decomposition of $\mathbf{D}\mathbf{D}^T$ is

$$\mathbf{K} \approx \mathbf{D}\mathbf{D}^T = (\mathbf{D}\mathbf{U}_S \mathbf{\Lambda}_S^{-1/2}) \mathbf{\Lambda}_S (\mathbf{D}\mathbf{U}_S \mathbf{\Lambda}_S^{-1/2})^T$$

It costs only $\mathcal{O}(nd^2)$ time and $\mathcal{O}(nd)$ space.

Problem:

- How to select informative columns of $\mathbf{K} \in \mathbb{R}^{n \times n}$ to construct $\mathbf{C} \in \mathbb{R}^{n \times c}$?
- The approximation error $\|\mathbf{K} - \mathbf{C}\mathbf{C}^T\|_F$ or $\|\mathbf{K} - \mathbf{C}\mathbf{C}^T\|_2$ should be as small as possible.

Hardness:

- Totally $\binom{n}{c}$ choices.

Theories

The adaptive sampling algorithm [Deshpande *et al.*, 2006]:

- 1 Sample c_1 columns of \mathbf{K} to construct \mathbf{C}_1 using some algorithm;
- 2 Compute the residual $\mathbf{B} = \mathbf{K} - \mathbf{C}_1 \mathbf{C}_1^\dagger \mathbf{K}$;
- 3 Compute sampling probabilities $p_i = \frac{\|\mathbf{b}_i\|_2^2}{\|\mathbf{B}\|_F^2}$, for $i = 1$ to n ;
- 4 Sample further c_2 columns of \mathbf{K} in c_2 i.i.d. trials, in each trial the i -th column is chosen with probability p_i ;
Denote the selected columns by \mathbf{C}_2 ;
- 5 Return $\mathbf{C} = [\mathbf{C}_1, \mathbf{C}_2]$.

Efficient Algorithms
Theories

- The error term $\|\mathbf{K} - \mathbf{C}\mathbf{C}^\dagger\mathbf{K}\|_F$ is bounded theoretically, but $\|\mathbf{K} - \mathbf{C}\mathbf{W}^\dagger\mathbf{C}^T\|_F$ is not.
- Empirically, the adaptive sampling algorithm works very well.

Compute the intersection matrix by

$$\mathbf{U} = \mathbf{C}^\dagger \mathbf{K} (\mathbf{C}^\dagger)^T = \mathbf{T}_1 (\mathbf{W} + \mathbf{T}_2 + \mathbf{T}_2^T + \mathbf{T}_3) \mathbf{T}_1^T,$$

where the intermediate matrices are computed by

$$\begin{aligned} \mathbf{T}_0 &= \mathbf{K}_{21}^T \mathbf{K}_{21}, & \mathbf{T}_1 &= \mathbf{W}^{-1} (\mathbf{I}_c + \mathbf{W}^{-1} \mathbf{T}_2)^{-1}, \\ \mathbf{T}_2 &= \mathbf{T}_0 \mathbf{W}^{-1}, & \mathbf{T}_3 &= \mathbf{W}^{-1} (\mathbf{K}_{21}^T \mathbf{K}_{22} \mathbf{K}_{21}) \mathbf{W}^{-1}. \end{aligned}$$

The four intermediate matrices are all of size $c \times c$, and the matrix inverse operations are on $c \times c$ small matrices.

Theorem (Exact Recovery.)

For the symmetric matrix \mathbf{K} defined previously, the following three statements are equivalent:

- 1 $\text{rank}(\mathbf{W}) = \text{rank}(\mathbf{K})$,
- 2 $\mathbf{K} = \mathbf{C}\mathbf{W}^\dagger\mathbf{C}^T$,
(i.e., the standard Nyström method is exact)
- 3 $\mathbf{K} = \mathbf{C}(\mathbf{C}^\dagger\mathbf{K}(\mathbf{C}^\dagger)^T)\mathbf{C}^T$,
(i.e., the modified Nyström method is exact)

Theorem (Exact Recovery.)

It holds in general that

$$\|\mathbf{K} - \mathbf{C}(\mathbf{C}^\dagger \mathbf{K} (\mathbf{C}^\dagger)^T) \mathbf{C}^T\|_F \leq \|\mathbf{K} - \mathbf{C} \mathbf{W}^\dagger \mathbf{C}^T\|_F.$$

It is because

$$\mathbf{U} = \mathbf{C}^\dagger \mathbf{K} (\mathbf{C}^\dagger)^T$$

is the solution to the problem

$$\min_{\mathbf{U}} \|\mathbf{K} - \mathbf{C} \mathbf{U} \mathbf{C}^T\|_F.$$
